

CLINICAL STUDY REPORT SUMMARY

Study ID: CT-001 | Trial Phase: II | July 25, 2025
Prepared by: Lana Zhang | Department of Biostatistics and Data Science

Study Summary

This clinical study report summarizes a simulated Phase II randomized controlled trial evaluating the baseline comparability and safety profile of Drug B versus Placebo.

The dataset consists of 11,878 patient-level records drawn from a synthetic Excel file ('patients_raw_data.xlsx'), representing demographic, cost, and adverse event data from a real-world-inspired clinical scenario. Data were cleaned, standardized, and mapped according to CDISC conventions to produce compliant SDTM and ADaM domains.

- Key deliverables in this report include:
- Table 1: Snapshot of cleaned patient data for verification.
 - Table 2: Baseline demographic and clinical characteristics by treatment group, with statistical comparison.
 - Table 3: Frequency and distribution of common adverse events by treatment group.
 - Figure 1: Distribution and statistical comparison of patient age across treatment arms.
 - Figure 2: Stratified boxplot of BMI by sex and treatment group.

All results support the quality and balance of randomization, and no significant safety signals were observed.

Table-1: Patient Characteristics Snapshot After Cleaning

Table 1. Patient Characteristics Snapshot After Cleaning

This table lists the first 100 observations from the cleaned dataset. It includes key variables such as subject ID, sex, age, treatment group, enrollment dates, BMI, weight status, lab results, and cost information.

The data provides a quick validation of the standardization and deduplication steps performed during the preprocessing phase.

★ Table 2. Baseline Characteristics by Treatment Group

This table compares key baseline characteristics across three treatment groups: Missing (N=112), Drug B (N=5905), and Placebo (N=5973). A total of 11,878 patients were included in the analysis. Age was approximately balanced across groups, with a mean of 41.2 years in the Drug B group and 41.7 years in the Placebo group. The Kruskal-Wallis test showed no statistically significant difference in age (P=0.2732). BMI was also similar among groups, with a mean of 21.3 kg/m² across both Drug B and Placebo. No significant difference was observed (P=0.6165). In terms of BMI categories (cWeight), nearly half of the participants fell into the 'Normal weight' group across all arms (49.1%), and about 28% were classified as 'Underweight'. The proportion of 'Obese' and 'Morbidly Obese' subjects was low (<5%). Chi-square testing indicated no significant group difference (P=0.8479). The average cost variable was normally distributed with similar means across groups: 64.4 in Drug B and 64.3 in Placebo. There was no significant difference (P=0.5427). Overall, the randomization process appears to have achieved baseline balance across treatment groups, supporting the validity of downstream comparative analyses.

Frequency Missing = 112

★ Table 3. Adverse Events Summary by Treatment Group

This table summarizes the frequency of two common adverse events (AEs) — Headache and Nausea — across the Drug B and Placebo treatment groups. A total of 11,878 observations were included (112 records had missing AE information). Headache was reported in 49.55% of Drug B and 50.45% of Placebo participants. Nausea occurred in 49.88% and 50.12% of participants in the respective groups. AE frequencies were nearly identical between groups. The Chi-square test yielded a non-significant result ($\chi^2=0.1343$, $df=1$, $P=0.7140$), indicating no statistically significant difference in adverse event distribution between treatment groups. Other tests, including the likelihood ratio and Fisher's exact test, corroborated this conclusion (two-sided $P=0.7273$). The effect size measures (Phi coefficient, Cramer's V) were close to zero, reinforcing the interpretation that the observed differences are minimal and likely due to chance. Overall, no evidence was found of an association between treatment group and the occurrence of reported adverse events.

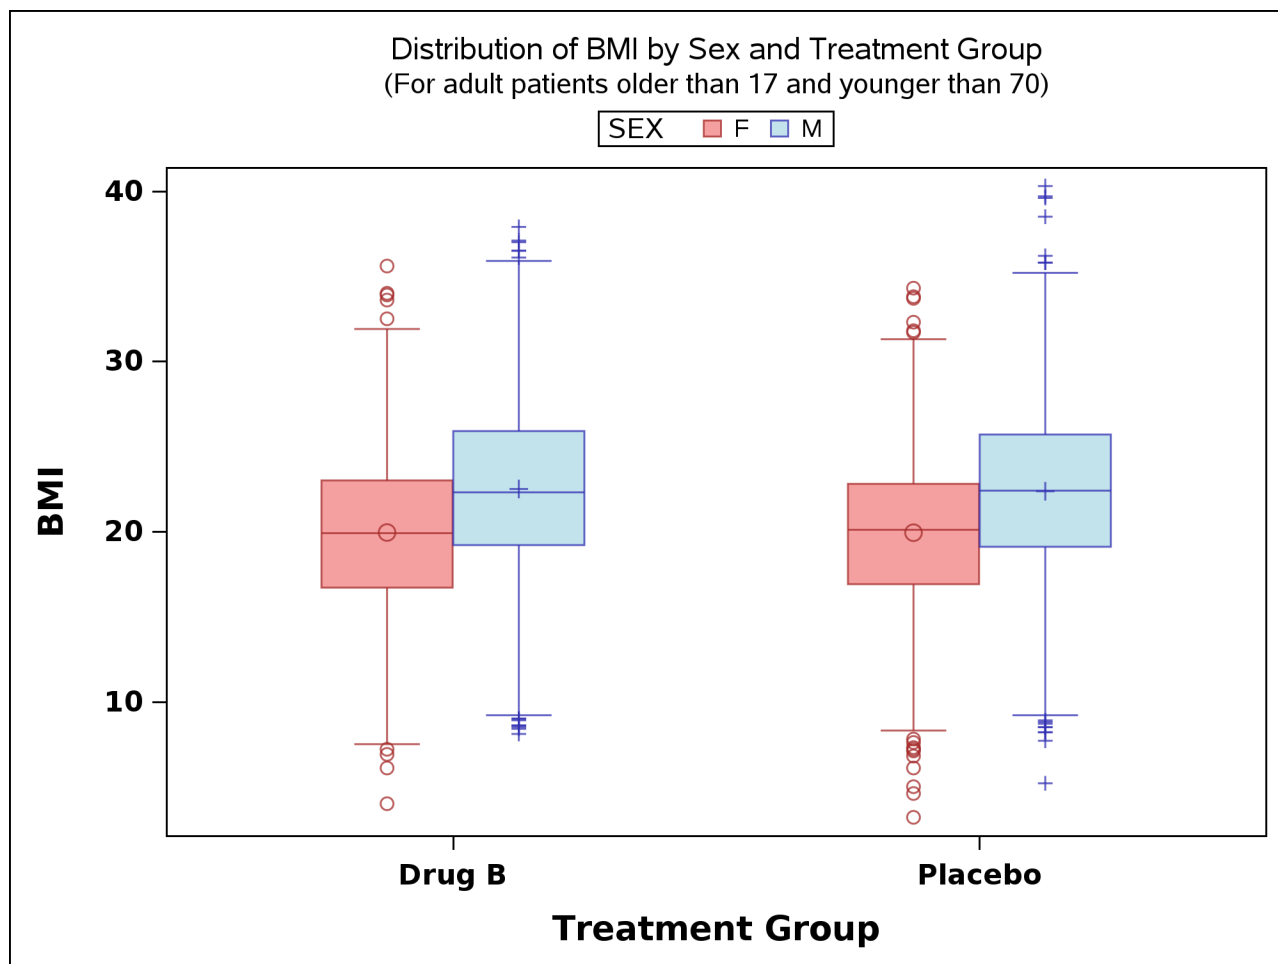

Figure-1
Distribution of Patient Age Stratified by Treatment Group

Variable: Age

★ Figure 1. Distribution of Patient Age Stratified by Treatment Group

The figure illustrates the distribution of age by treatment arm using a combination of histogram, summary panel, and Q-Q plots. The TTEST procedure also provides statistical comparison between groups. The histogram, kernel density, and normal distribution overlays demonstrate that age is approximately uniformly distributed in both groups with similar ranges and central tendencies. The boxplots further confirm that age distributions are comparable, supporting the assumption of group balance for age.

★ **Figure 2. Boxplot of BMI by Sex and Treatment Group**

This boxplot shows BMI distributions across treatment groups, further stratified by sex. Adult patients aged 17–70 were included in this figure. Boxplots indicate that both males and females in the Drug B and Placebo groups show similar BMI medians and interquartile ranges. There are visible outliers, especially among males, but overall group-level BMI distributions appear balanced, suggesting no baseline BMI confounding between treatment groups.
